Université catholique de Louvain (UCL), Louvain-la-Neuve, Belgium

**Do you want your June contribution to be automatically included in subsequent reports? (If yes, you may still update your contribution via a form like this one.)**

No do not use my prediction this month in later months

**What is the type of you outlook projection?**

Dynamic Model

**Starting in 2017 we are accepting both pan-Arctic and pan-Antarctic sea ice extent (either one or both) of the September monthly mean. As in 2016, we are also collecting Alaskan regional sea ice extent. To be consistent with the validating sea ice extent index from NSIDC, if possible, please first compute the average sea ice concentration for the month and then compute the extent as the sum of cell areas > 15%.**

**a) Pan-Arctic September extent prediction in million square kilometers.**

3.8

**b) same as in (a) but for pan-Antarctic. If your method differs substantially from that for the Arctic, please enter it as a separate submission.**

18.2

**c) same as in (b) but for the Alaskan region. Please also tell us the maximum possible extent if every ocean cell in your region were ice covered.**

Sea Ice Outlook  
2017 June Report  
Individual Outlook

---

**"Executive summary" of your Outlook contribution (using 300 words or less) describe how and why your contribution was formulated. To the extent possible, use non-technical language.**

Our estimate is based on results from ensemble runs with the global ocean-sea ice coupled model NEMO-LIM3. Each member is initialized from a reference run on May 31, 2017, then forced with the NCEP/NCAR atmospheric reanalysis from one year between 2007 and 2016. Our final estimate is the ensemble median, and the given range corresponds to the lowest and highest extents in the ensemble.

**Brief explanation of Outlook method (using 300 words or less).**

Our estimate is based on results from ensemble runs with the global ocean-sea ice coupled model NEMO-LIM3. The ensemble members are expected to sample the atmospheric variability that may prevail this summer. In practice, the model is forced with NCEP/NCAR atmospheric reanalysis data from 1948 to May 31, 2017. No data are assimilated during this simulation. Ten ensemble members are then started from the obtained model state, each using atmospheric forcing from one year between 2007 and 2016. This choice is a compromise between a sufficiently large ensemble and the rapidly changing Arctic atmospheric conditions in recent decades. The estimate given above corresponds to the ensemble median monthly September extent, corrected by the mean bias between simulated and observed values reported in the NSIDC sea ice index, which equals 0.6 million square kilometers. The model configuration is exactly the same as in our last four years contributions. Additional details can be found in our 2013 reports.

**Tell us the dataset used for your initial Sea Ice Concentration (SIC). Include name and date (e.g., "NASA Team, May 2017"). We also encourage you to submit initial fields to the dropbox, see <https://www.arcus.org/sipn/sea-ice-outlook/2017/june/call> in the section on "Submitting Figures and Gridded Data of Full Spatial Fields (Optional) of Forecasts and Initial Conditions" for detailed instructions. Required if sea Ice concentration is used.**

Initial sea ice concentrations come from a model free run on May 31.

**Dataset of initial Sea Ice Thickness (SIT) used (include name and date):**

Initial sea ice thicknesses come from a model free run on May 31.

**If you use a dynamic model, please specify the name of the model as a whole and each component including version numbers and how the component is initialized:**

Ocean - NEMO 3.5 - initialized on May 31 from a free run

Sea ice - LIM3 - initialized on May 31 from a free run

**If available from your method for pan-Arctic extent prediction, please provide:**

Sea Ice Outlook  
2017 June Report  
Individual Outlook

---

**a) Uncertainty/probability estimate such as median, ranges, and/or standard deviations (specify what you are providing).**

Projection uncertainty range:

- Arctic: from 2.4 to 4.5 million square kilometers
- Antarctic: from 17.5 to 18.7 million square kilometers

**b) Brief explanation/assessment of basis for the uncertainty estimate (1-2 sentences).**

The projection uncertainty is given as the range between minimum and maximum extents in the ensemble. Although relatively wide, this neglects potential erroneous initial state and model errors not accounted for through the mean bias correction. It is based solely on the uncertainties arising from atmospheric variability, and on the hypothesis that the 2017 atmospheric summer conditions will be similar to the ones observed during the last decade.

**c) same as in (b) but for the Alaskan region. Please also tell us the maximum possible extent if every ocean cell in your region were ice covered. See <https://www.arcus.org/sipn/sea-ice-outlook/2017/june/call> in the section on "Instructions for Submitting an Alaskan Regional Outlook" for detailed instructions.**

The September sea ice extents from the ensemble members have been corrected by the mean bias between the observed (from the NSIDC sea ice index) and simulated (by the reference NEMO-LIM3 run) extents over 2007-2016, which equals 0.6 million square kilometers.

**d) Raw (and/or post processed) forecasts for this year and retrospective forecasts in an excel spreadsheet with one year on each row and ensemble member number on columns (specifying whether raw or post processed).**

The September sea ice extents from the ensemble members have been corrected by the mean bias between the observed (from the NSIDC sea ice index) and simulated (by the reference NEMO-LIM3 run) extents over 2007-2016, which equals 0.6 million square kilometers.
